# 1. Introduction

## □ The exposure of chlorinated organic can cause threats to human beings

- Carcinogenic and cytotoxic effects that can cause severe damage to central nervous system, endocrine system and immune system
- Listed as one of the priority pollutants by the US Environmental Protection Agency

## □ Soil Pollution Prevention and Control

### Soil Pollution Prevention and Control Law of the People's Republic of China

中华人民共和国土壤污染防治法

(2018年8月31日第十三届全国人民代表大会常务委员会第五次会议通过)

# 1. Introduction

## □ Remediation technology

### ■ Bioremediation

Many anaerobic bacteria reductively dechlorinate PCE or TCE to vinyl chloride and ethene (e.g., *Desulfuromonas*, *Sulfurospirillum multivorans*, and *Dehalobacter*).

#### The challenges of bioremediation:

- Low dechlorination rates and long clean up times;
- Inefficient supply of suitable electron donors to the dechlorinating bacteria;
- Toxicity of high PCE or TCE concentrations to dechlorinating bacteria.

Need to combine other technology with various bacteria to improve the removal efficiency of chlorinated-solvent contaminated groundwater

# 1. Introduction

## □ Remediation technology

### ■ Nanoscale zero-valent iron (nZVI)

Modified

### ■ Layered double hydroxides (LDHs)

LDHs are widely used as catalysts, sorbents, due to the layered structure, high anionic exchange capability, large surface area, high porosity and thermal stability

### The challenges for field applications of nZVI:

- The agglomeration of nZVI particles;
- nZVI particles are oxidized spontaneously;
- nZVI particles exhibited severe toxicity on cell growth;

- A combined nZVI-LDH+bacteria system for PCE remediation will result in more removal efficiency and benign end products because of microbial actions.
- The degradation kinetics and efficiency of PCE by nZVI-LDH and acclimated microbial consortium were investigated

# 2. PCE biodegradation by microbial consortium

## Composition of the acclimated microbial consortium

- the acclimated microbial consortium mainly consisting of *Clostridium sp.* FCB45 (44.49%), *Methylotrophic bacterium* RS X3 (17.34%), *Rhodocyclales bacterium* TP139 (7.39%), *Desulfovibrio* (2.61%), and *Treponema* (0.85%) at species level;
- 0.5-2.5 mg/L PCE could be completely biodegradation within four days.

## 2. PCE biodegradation by microbial consortium

### Effect of pH and temperature on PCE biodegradation

- The highest PCE biodegradation rate was observed at temperature of 30°C, in neutral pH.
- The acclimated microbial consortium had a potential for in situ PCE bioremediation.

# 2. PCE biodegradation by microbial consortium

## Effect of co-substrate on PCE biodegradation

- The biodegradation rate: Yeast extract > Glucose ≈ Methanol > Sodium lactate > No co-substrates > Ethanol;
- The enhanced biodegradation process followed the first-order reaction kinetics.

| Co-substrates    | First order kinetic model                   | R <sup>2</sup> | K     | T <sub>1/2</sub> (d) |
|------------------|---|----------------|-------|----------------------|
| Methanol         | $y = 1.39 * e^{-\frac{x}{7.02}} - 0.682$    | 0.972          | 0.142 | 1.138                |
| Ethanol          | $y = 4.38 * e^{-\frac{x}{27.23}} - 3.67$    | 0.928          | 0.037 | 1.338                |
| Glucose          | $y = 1.62 * e^{-\frac{x}{6.875}} - 0.792$   | 0.963          | 0.145 | 1.555                |
| Yeast extract    | $y = 1.11 * e^{-\frac{x}{3.055}} - 0.223$   | 0.988          | 0.327 | 1.309                |
| Sodium lactate   | $y = 1.895 * e^{-\frac{x}{8.906}} - 1.106$  | 0.955          | 0.112 | 1.474                |
| No co-substrates | $y = 1.746 * e^{-\frac{x}{10.155}} - 1.061$ | 0.884          | 0.098 | 1.137                |

## 2. PCE biodegradation by microbial consortium

### Effect of rhamnolipid and tween 80 on PCE biodegradation

When the rhamnolipid and tween 80 were at 10 mg/L and 50 mg/L, the PCE biodegradation efficiency was enhanced to 73% and 67%, respectively.

# 3. Degradation of PCE by nZVI-LDH

Layered double hydroxide (LDH) modified nanoscale zero-valent iron (nZVI-LDH) was prepared by co-precipitation method with nZVI as the core and LDH as the shell.

# 3. Degradation of PCE by nZVI-LDH

|          | The removal rate constant ( $\text{h}^{-1}$ ) | $R^2$ |
|----------|---|-------|
| nZVI     | 0.12  | 0.935 |
| nZVI-LDH | 0.23  | 0.924 |

- ❑ The removal efficiency of PCE by nZVI and nZVI-LDH were 81.5% and 96.3% respectively after 24 h.
- ❑ The kinetic analysis demonstrated that PCE degradation follows pseudo first order kinetic behavior.

# 3. Degradation of PCE by nZVI-LDH

- When the initial PCE concentrations increased, more  $\text{Fe}^0$  would be oxidized and would lose its activity leading to a decrease in the removal rate;
- The efficiency of PCE degradation decreased with the increase in pH, indicating that nZVI-LDH could remove PCE in groundwater more effectively at acidic pH values than alkali pH values.

# 3. Degradation of PCE by nZVI-LDH

- ❑ PCE removal as obviously promoted in the presence of co-existing Cu<sup>2+</sup> ions, while inhibited in the presence of co-existing Ca<sup>2+</sup> and Mg<sup>2+</sup> ions.
- ❑ The performance of PCE degradation was inhibited slightly by the common groundwater anions;

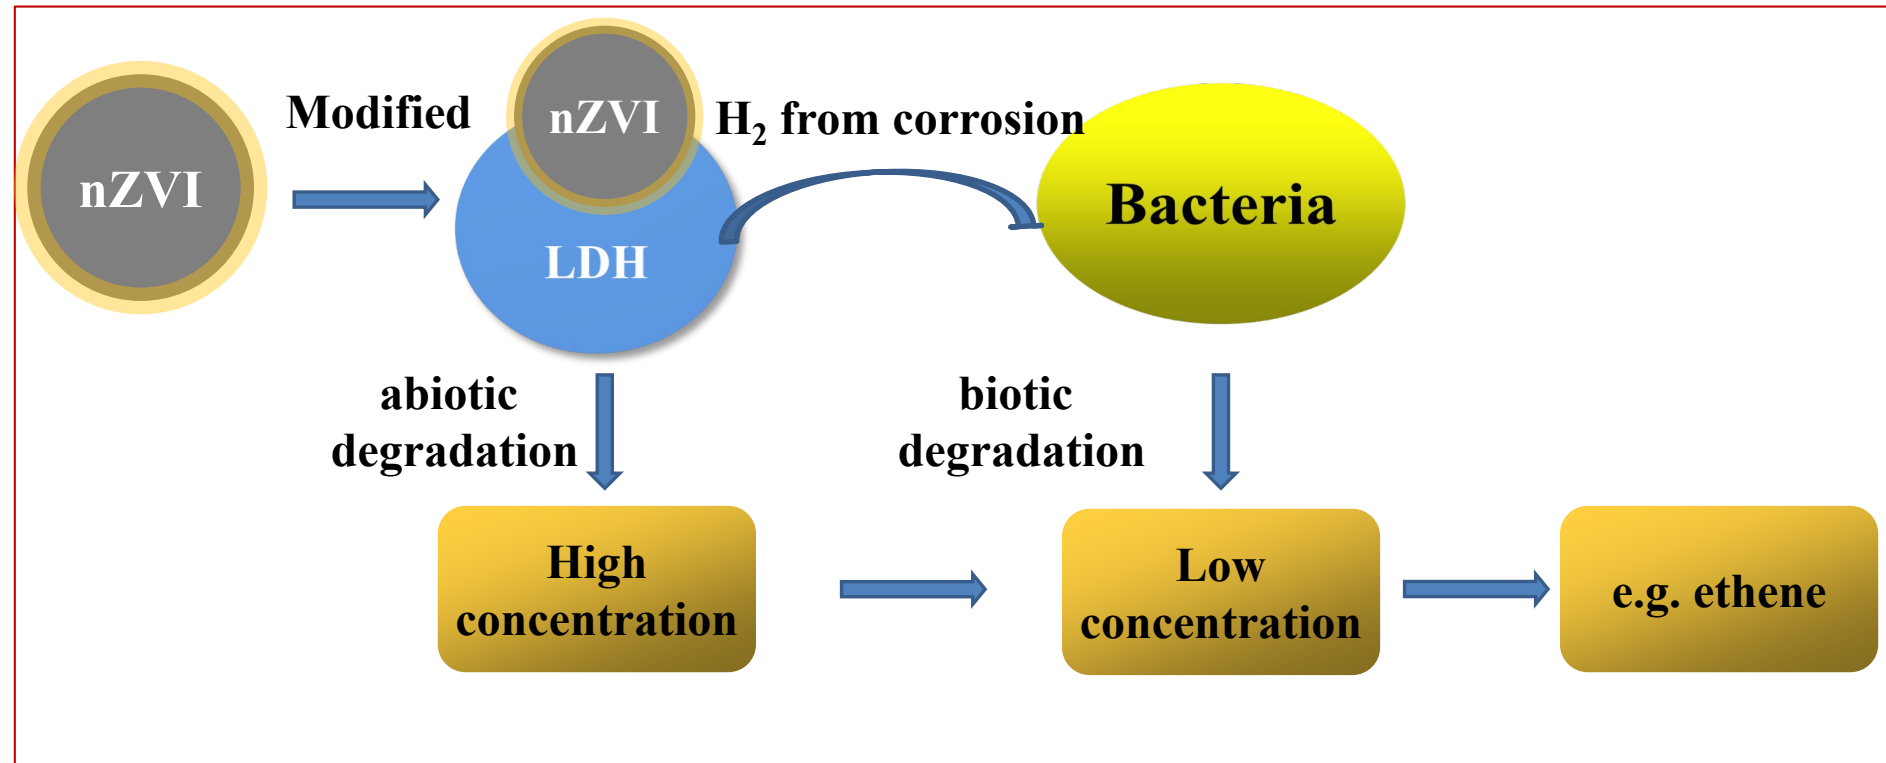

# 4 Coupled degradation of PCE by bacteria and nZVI-LDH

- For the combined nZVI-LDH+bacteria system, the removal rate of PCE was higher than that of PCE-degrading consortium;
- The degradation of PCE followed the pseudo-first order reaction kinetics, the degradation rate constant was 0.16 and 0.55 d<sup>-1</sup>, respectively.

# 4 Coupled degradation of PCE by bacteria and nZVI-LDH

## ■ nZVI-LDH+microorganism

PCE was degraded by nZVI-LDH to lower concentration at the initial stage, which was conducive to the growth of microorganisms. In addition, the addition of nZVI-LDH can create reducing conditions and produce hydrogen as electron donor, enhancing the PCE biodegradation efficiency.

## 5. Conclusions

---

- The enriched PCE-degrading consortium consisted of 44.49% *Clostridium* and other potential PCE degraders; 0.5-2.5 mg/L PCE could be completely biodegradation within four days.
- The optimal temperature and pH for PCE biodegradation were 30°C and pH 7; When the rhamnolipid and tween 80 were at 10 mg/L and 50 mg/L, the PCE biodegradation efficiency was enhanced to 73% and 67%, respectively.
- The PCE degradation by nZVI-LDH could be well described by pseudo first order model; The degradation efficiency of PCE decreased with the initial pH increased;
- The presence of Cu<sup>2+</sup> improved degradation efficiency of PCE by nZVI-LDH due to its role as a catalyst or medium of charge transfer during reduction;
- Enhanced biodegradation of PCE by coupling nZVI-LDH and PCE-degrading consortium was observed.

**Welcome to Nanjing, China!**
